Outline of the presentation

- ❖ Polarized gamma beams: scenario for future measurements on the depolarization ratio for the case of ^{12}C with triangular and more exotic structures
- ❖ Transition densities in action for ^{12}C and ^{16}O , recent results on alpha-transfer form factors
- ❖ New insight on the structure of ^{29}F at the border of the island of inversion

Discrete symmetries and polarized gamma-rays in ^{12}C

PHYSICAL REVIEW C **99**, 031302(R) (2019)

Rapid Communications

Editors' Suggestion

Establishing the geometry of α clusters in ^{12}C through patterns of polarized γ rays

Lorenzo Fortunato

*Dipartimento di Fisica e Astronomia "G. Galilei"-Università di Padova, via Marzolo 8, I-35131 Padova, Italy
and INFN-Sez. di Padova, via Marzolo 8, I-35131 Padova, Italy*

 (Received 13 December 2018; published 11 March 2019)

One can shoot linearly polarized gamma rays (Electric field oscillating in a given direction constant in time) of appropriate energy (tuned to match the resonances of interest) and observe the outgoing gammas of the same or different energies with a polarizer/analyzer. If the nucleus has a definite geometrical symmetry (i.e. if there is an underlying discrete group structure), very strict selection rules apply. Experimentally the polarization can be measured with another inverse Compton scattering.

Polarized gamma-ray facilities around the globe:

- ❑ Mainz Microtron MAMI (Continuous Wave, beam polarization 80%, En. resol. 0.1 MeV, but energy too high 50-800 MeV)
- ❑ Triangle University Higgs facility (FEL type, quasi CW operation, 2-60 MeV, flux 10^8 - 10^9 phot./s)
- ❑ ELI-NP in Romania (0-20 MeV, high flux, high resolution, 100% polarization)
- ❑ LEPS – Japan (very high energy)
- ❑ NewSubaru
- ❑ ...

Gamma beam parameter	Value
Energy [MeV]	0.2 – 19.5
Spectral density [ph/s/eV]	$0.8 - 4 \cdot 10^4$
Bandwidth rms [%]	≤ 0.5
#Photons/shot within FWHM bdw.	$\leq 2.6 \cdot 10^5$
#Photons/s within FWHM bdw.	$\leq 8.3 \cdot 10^8$
Source rms size [μm]	10 – 30
Source rms divergence [μrad]	25 – 200
Peak brilliance [$N_{\text{ph}}/\text{s} \cdot \text{mm}^2 \cdot \text{mrad}^2 \cdot 0.1\% \text{bdw}$]	$10^{20} - 10^{23}$
Pulse length rms [ps]	0.7 – 1.5
Linear polarization [%]	> 99
Macro repetition rate [Hz]	100
Number of pulses/macropulse	32
Pulse-to-pulse separation [ps]	16

With the advent of the new facility in Romania, beams of high brilliance, focused, polarized gamma rays produced with Inverse Compton Scattering will become available with energies ranging from 0.2-20 MeV

Depolarization ratio

One can measure the so-called **depolarization ratio** between intensities, by turning the analyzer/polarizer of 90 degrees, i.e.:

$$\rho = \frac{I_{\perp}}{I_{\parallel}}$$

as a tool to determine which modes are totally symmetric modes. In fact from the theory of Raman scattering

$$0 \leq \rho \leq \frac{3}{4} \quad \text{for polarized bands} \\ \text{(symmetric modes)}$$

$$\rho = \frac{3}{4} \quad \text{for depolarized bands} \\ \text{(non-symmetric modes)}$$

even with a **randomly oriented sample**.

Figure 8.6. Parallel and perpendicular Raman scattering.

Figure 8.8. Polarized light scattering by a sphere.

Figures from book by P. Bernath

Depolarization ratio : a chemical example CCl_4

This kind of measurements of $\rho = \frac{I_{\perp}}{I_{\parallel}}$ are absolutely standard in optical spectroscopy (where polarizers and analyzers are easy to do and handle).

Figure 2: Polarized Raman spectra of CCl_4 .

Figure from D.Tuschel – Spectroscopy (2014)

Depolarization ratio

Panoply of different models ... too many... just to name a few !!!

(Too) many models have been proposed for ^{12}C where the triangle is not equilateral, isosceles, scalene or even a linear chain (Morinaga). Therefore, I have set forth to determine all possible outcomes and the patterns that can be predicted are intended as a guidance as to which configuration is right and **the crucial method is clearly through measurements of the depolarization ratio in Raman-like experiments of nuclear fluorescence** that will be feasible at ELI-NP or in other labs where gamma-rays are available.

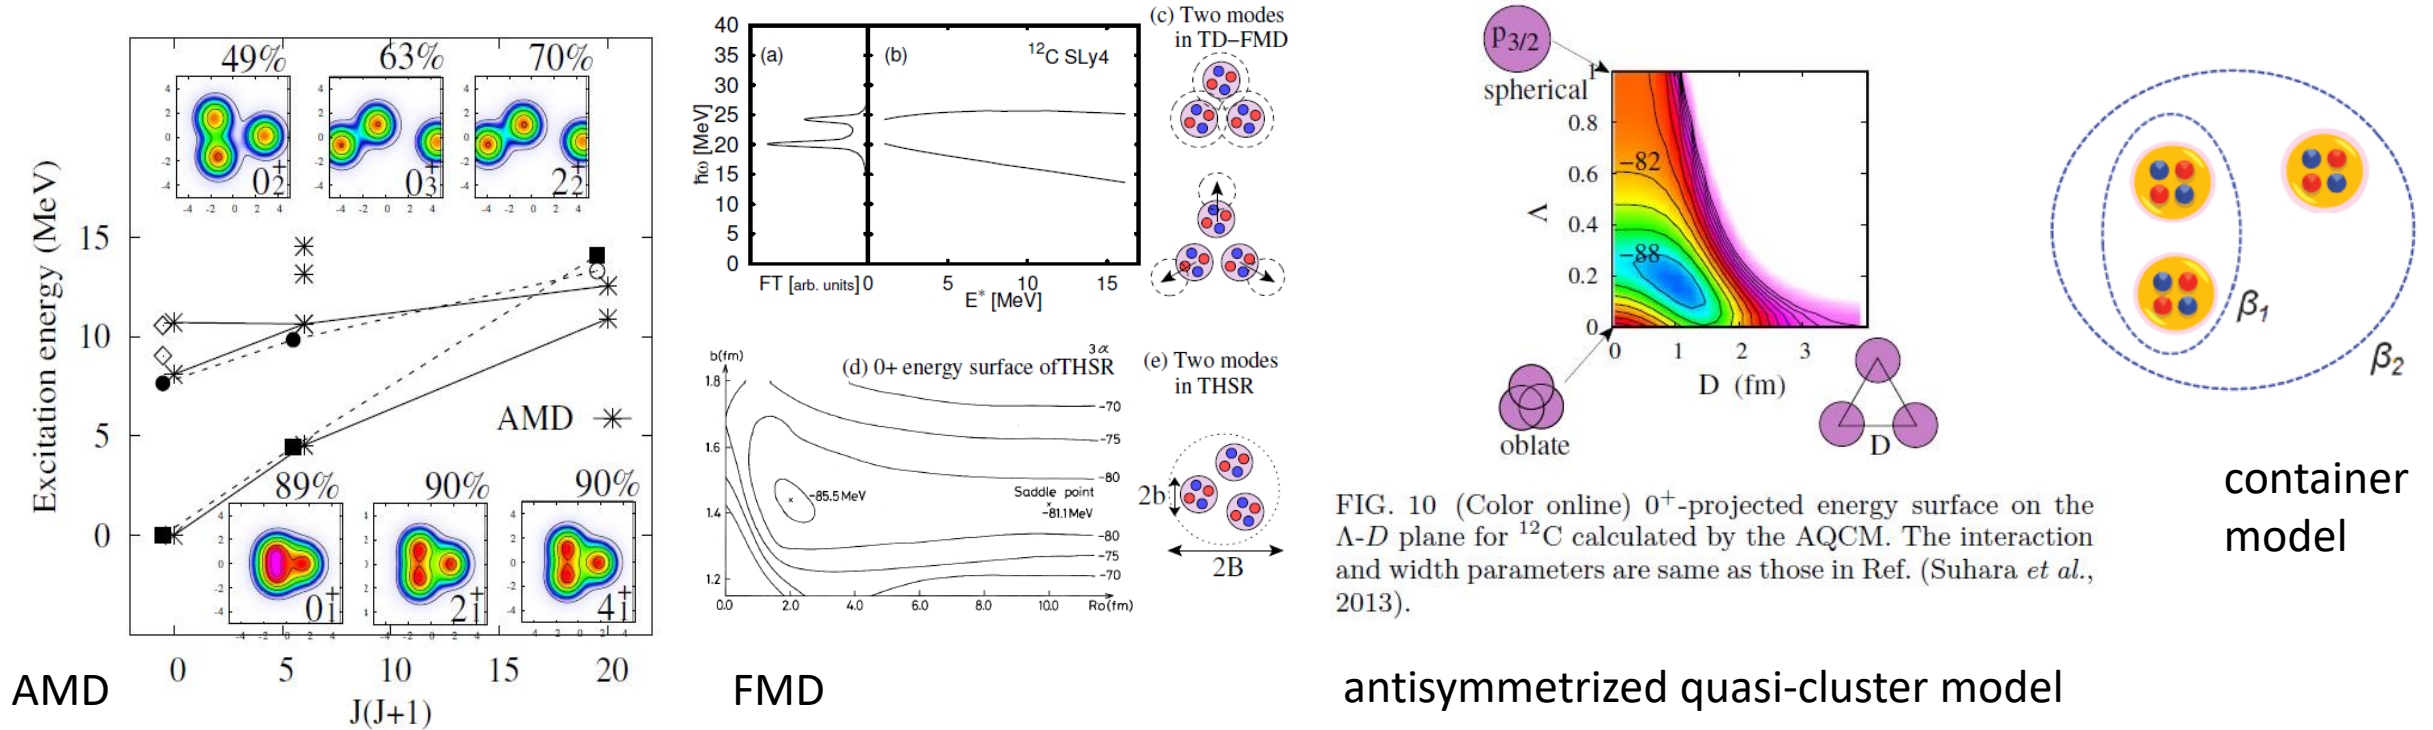

FIG. 10 (Color online) 0_1^+ -projected energy surface on the Λ - D plane for ^{12}C calculated by the AQCM. The interaction and width parameters are same as those in Ref. (Suhara *et al.*, 2013).

Algebraic cluster model for 3 alphas

Bijker and Iachello (Ann.Phys. 298, 2002) have clearly demonstrated the successful application of the ACM, or algebraic cluster model, to the vibrational-rotational spectrum of alpha-conjugate nuclei like ^{12}C and ^{16}O .

Note that rotational bands DO NOT conform to the usual quadrupole rotational bands we are used, they have a different symmetry!
Rather, these are the ways in which you can spin a triangle.

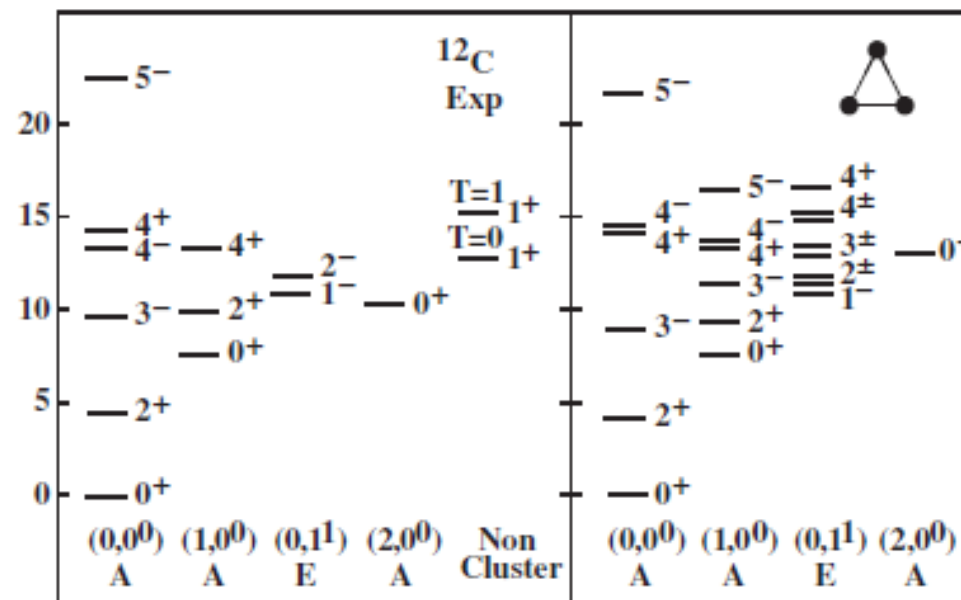

FIG. 2. Comparison between the low-lying experimental spectrum of ^{12}C [12] and that calculated using Eq. (6) with $A = 7.0$, $B = 9.0$, $C = 0.7$, and $D = 0.0$ MeV. States with uncertain spin-parity assignment are in parentheses.

Evidence for Triangular \mathcal{D}_{3h} Symmetry in ^{12}C

D. J. Marín-Lámbari,¹ R. Bijker,² M. Freer,¹ M. Gai,^{3,4} Tz. Kokalova,¹ D. J. Parker,¹ and C. Wheldon¹

This lovely paper confirms the assignment of the 5- state at 22.4(2) MeV to the g.s. band of an **equilateral triangular structure**.

Note the uncommon spin-parity of bands (the doublet 4+/ 4- has a natural explanation in terms of \mathcal{D}_{3h} symmetry!).

Working plan to implement this idea

Work plan:

- Decide arrangement of N particles
- This means $3N-6$ d.o.f (or $3N-5$ d.o.f. for linear arrangement)
- Identify the underlying discrete group structure
- Find the character under transformations of the group Γ_{3N}
- Subtract translations and rotations to single out character of vibrational modes Γ_{vib}
- Identify patterns of totally symmetric modes
- Check models against measures of intensities → Eureka !!

Tables in PRC 99 (2019) paper: 3 equal clusters

name	shape	group	Γ_{vib}	Patterns
linear =		$D_{\infty h}$	$A_{1g} + A_{1u} + E_{1u}$	
linear \neq		$C_{\infty v}$	$2A_1 + E_1$	
equilateral		D_{3h}	$A'_1 + E'$	
isosceles		C_{2v}	$2A_1 + B_1$	
scalene		C_s	$3A'$	

The number of totally symmetric peaks over total is different in each case, therefore one can disentangle the various possibilities

Tables in PRC 99 (2019) paper

There might be more than just one configuration! The picture complicates a little, but not too much ! One can invoke the concept of descent in symmetry and still apply some of the rules.

Group chains

 (Received 1 October 2019; published 21 January 2020)

Densities and transition densities are computed in an equilateral triangular α -cluster model for ^{12}C , in which each α particle is taken as a Gaussian density distribution. The ground state, the symmetric vibration (Hoyle state), and the asymmetric bend vibration are analyzed in a molecular approach and dissected into their components in a series of harmonic functions, revealing their intrinsic structures. The transition densities in the laboratory frame are then used to construct form factors and to compute distorted-wave Born approximation inelastic cross sections for the $^{12}\text{C}(\alpha, \alpha')$ reaction. The comparison with experimental data indicates that the simple geometrical model with rotations and vibrations gives a reliable description of reactions where α -cluster degrees of freedom are involved.

Ground state

This model assume gaussian densities for each alpha particle

$$\rho_{\alpha}(\vec{r}) = \left(\frac{\alpha}{\pi}\right)^{3/2} e^{-\alpha r^2}$$

and a total density that is the sum of three displaced alpha's

$$\rho_{\text{gs}}(\vec{r}, \{\vec{r}_k\}) = \sum_{k=1}^3 \rho_{\alpha}(\vec{r} - \vec{r}_k),$$

which is then expanded in spherical harmonics

$$\rho_{\text{gs}}(\vec{r}) = \sum_{\lambda\mu} \rho_{\text{gs}}^{\lambda,\mu}(r) Y_{\lambda,\mu}(\theta, \varphi),$$

Ground and Hoyle bands

In collaboration with A. Vitturi, E. Lanza and J. Casal

Ground state band

Hoyle state band

Parameters phenomenologically adjusted

TABLE I. Calculated observables within the ground-state band.

$\langle r^2 \rangle_{0_1^+}^{1/2}$	2.45 (fm)
$B(E2; 2_1^+ \rightarrow 0_1^+)$	7.86 ($e^2 \text{fm}^4$)
$B(E3; 3_1^- \rightarrow 0_1^+)$	65.07 ($e^2 \text{fm}^6$)
$B(E4; 4_1^+ \rightarrow 0_1^+)$	96.99 ($e^2 \text{fm}^8$)

TABLE II. Quantities calculated in the present work for the Hoyle band using the values of β and χ_1 given in the text.

$\langle r^2 \rangle_{0_2^+}^{1/2}$	3.44 (fm)
$B(E2; 2_2^+ \rightarrow 0_1^+)$	0.58 ($e^2 \text{fm}^4$)
$B(E2; 0_2^+ \rightarrow 2_1^+)$	2.90 ($e^2 \text{fm}^4$)
$B(E3; 3_2^- \rightarrow 0_1^+)$	70.42 ($e^2 \text{fm}^6$)
$M(E0; 0_2^+ \rightarrow 0_1^+)$	5.4 ($e \text{fm}^2$)

E-band

Transition densities \rightarrow Form Factors \rightarrow Coupled Channels \rightarrow Cross-sections

FIG. 15. Form factors in logarithmic scale for a few inelastic excitation processes of interest. We show the nuclear, Coulomb, and total form factors.

FIG. 16. Differential cross section for the elastic scattering and the transitions $0_1^+ \rightarrow 2_1^+$ and $0_1^+ \rightarrow 3_1^+$ at 240-MeV bombarding energy. Data are from Ref. [41] (retrieved through EXFOR).

Lots of results that I don't have time to discuss in details.

They confirm that with just a simple triangular model one catches all the gross features, not only of the nuclear structure, but also of reaction dynamics of ^{12}C .

Importance of the imaginary part of the ion-ion potential

$$V(r) + iW(r)$$

FIG. 17. Differential cross section for the transition $0_1^+ \rightarrow 0_2^+$ at 240-MeV bombarding energy. Data are from Ref. [41] (retrieved through EXFOR) and the three curves have different factors for the depth of the imaginary part as indicated in the figure.

3D transition density to first excited A band (0^+)

Expansion in spherical harmonics of the transition densities

Selection rule for alpha transfer

Taking into account the symmetric groups of 2-3-4 identical objects, one can up with a scheme for alpha-transfer (I mean the addition or removal of 1 alpha particle) based on Young tableaux, i.e. on the representations of those groups.

It turns out that not all of them can be connected, for instance one cannot go from the A states of ^{12}C to the E states of oxygen, the alpha transfer should be identically zero !

But,... violated in exp. data ?

Fig. 8 The representations of the systems with 4,3 and 2 α particles connected by arrows corresponding to processes of induction/restriction that amounts to the addition/removal of one box from the corresponding Young diagrams

The ^{29}F nucleus as a lighthouse on the coast of the island of inversion

L. Fortunato ^{1,2}✉, J. Casal ^{1,2}, W. Horiuchi ³, Jagjit Singh ⁴ & A. Vitturi^{1,2}

Fluorine-29 stands on the coast of the island of inversion

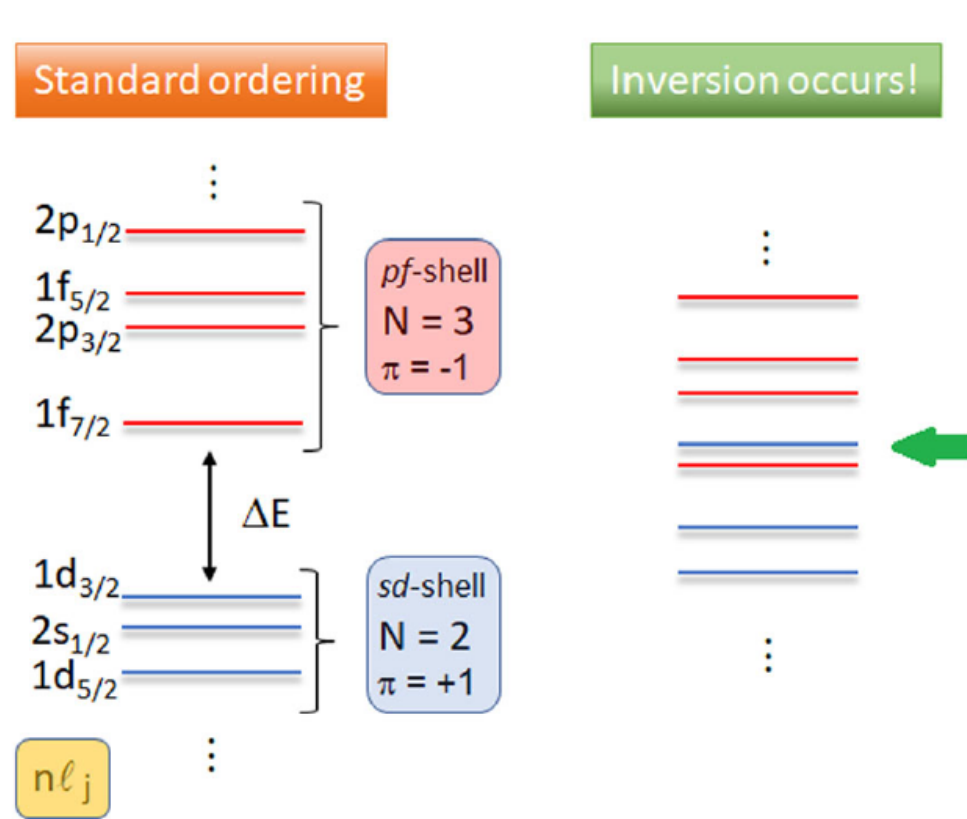

Fig. 1 Standard ordering of shell-model energy levels and typical inversion mechanism. The $N = 2$ sd -shell and the $N = 3$ pf -shell with positive and negative parity π , respectively, are shown on the left in the standard ordering (states are labeled by the standard set of quantum number $n\ell_j$). Inversion occurs (right) when the shell gap, ΔE , associated with the filling of 20 neutrons, disappears and one level (or more) of the $N = 3$ pf -shell gets lower than one (or more) of the levels of the $N = 2$ sd -shell.

Fig. 2 Synopsis of known experimental data on $^{28,29}\text{F}$. All energies are in keV (not to scale) from refs. ^{4-6,11}. States in red are labelled by the J^π quantum numbers and energies are referred to the $^{27}\text{F} + 2n$ threshold. States in blue are inferred from the $^{29}\text{F}(-1n)$ column of Fig. 2 of ref. ⁶, and correspond only to the states decaying to the ground state of ^{27}F . They are labelled by the orbital angular momentum quantum number, ℓ , when available. Energies are referred to the $^{27}\text{F} + n$ threshold.

Fluorine-29 stands on the coast of the island of inversion

We had previously PRC **101**, 024310 (2020) proposed 4 scenarios for the structure of the very exotic nucleus ^{29}F , called A,B,C,D , based on the three-body hyperspherical formalism by J.Casal

FIG. 1. $^{27}\text{F} + n$ phase shifts for $d_{3/2}$, $p_{3/2}$, and $f_{7/2}$ states, corresponding to different sets (A–D). The dotted black line corresponds to $\pi/2$.

Fluorine-29 stands on the coast of the island of inversion

Fig. 4 Results on ^{29}F within the new D^b scenario. **a** Ground-state probability density of ^{29}F as a function of the distance between the two valence neutrons (r_{nn}) and that between their center of mass and the core (r_{c-nn}). The maximum probability density corresponds to the dineutron configuration. **b** Electric dipole (E1) strength function from the ground state to continuum as a function of the $^{27}\text{F} + n + n$ energy. The dashed line indicates the cumulative integral. The dash-dotted line is the corresponding Relativistic Coulomb Excitation (RCE) cross-section, scaled to the same maximum to illustrate the decreasing proportionality with the energy.

Summary

- ✓ **PRC 99 (2019)** I have suggested to use the **highly polarized monochromatic gamma rays** that will be available at ELI-NP as a **tool to study the molecular vibrations of clusterized nuclei**, taking as a definite example the ^{12}C nucleus as composed of 3 α particles. A **measure of depolarization ratio** could be done in a sort of Raman nuclear fluorescence experiment. This would yield **precise patterns of vibrational spectra**, that will **correlate directly** with a given **geometric configuration** possessing a **discrete point-group symmetry**.
- ✓ **PRC 101, 014315 (2021)** We have calculated **transition densities and form factors for ^{12}C** in a triangular molecular model for the g.s., A and E bands. We applied this model to **$^{12}\text{C} + \alpha$ scattering** showing a very good agreement.
- ✓ **EPJA 57 (2021)** We have **extended these results to ^{16}O in a tetrahedral** arrangement and we have calculated **alpha-induced reaction** observables. I have found a **new selection rule for alpha-transfer** based on group theory.
- ✓ **Comm.Physics 3 (2020)** and also **PRC 101, 024310 (2020)** We have successfully interpreted new experimental results on the **structure of ^{29}F** indicating it lies **at the border of the island of inversion**.

A few points for discussion

- if the g.s. rotational band contains the same multipolarity that one is trying to excite in the vibrational bands, this is also to be included in the above patterns.
- in principle the degree of polarization might be close to $3/4$ also for polarized (A) bands, therefore it might become hard to distinguish between them
- non-cluster degrees of freedom might come into play at a certain energy, thus blurring the picture
- in nuclei with a cluster structure including t or h clusters, the interplay with single-particle orbits around a molecular center might also be very relevant
- I guess a BEC gas would show no geometric arrangements (no equilibrium points) and would behave as an $L=0$ state (a sphere), thus offering only 1 such bands of A type (polarized).

A word of caution

DISCLAIMER for the first topic:

- It is perfectly clear to us that molecular models of nuclei are **FUNDAMENTALLY DIFFERENT** from molecular physics, where the Born-Oppenheimer approximation is valid and one can think of nuclear motion as a small vibration, happening only close to the minimum of a very deep potential energy surface (in molecular energy scales).
- Nuclei have large kinetic energy $\langle T \rangle$, comparable to the potential energy $\langle V \rangle$ and the zero point motion inside the P.E.S. is a large fraction of the well depth, therefore there are **LARGE FLUCTUATIONS** around the equilibrium points and we **SHOULD NOT EXPECT** that the vibrational levels are deeply lying in the potential well, at most they can be weakly bound states, close to threshold, or more probably resonances in the continuum!
- Despite this, it is instructive to look at
 1. the normal modes, i.e. the «best» internal coordinates
 2. symmetry-adapted vibrational orbitals
 3. the energy scale and structure of the vibrational levels

Nomenclature

Table II: The Mulliken symbols used to describe the symmetry species of point groups including their meaning with respect to molecular symmetry	
Mulliken Symbols of Symmetry Species (Column 1 In Character Table)	Meaning
<i>A</i>	Symmetric with respect to principal axis of symmetry
<i>B</i>	Antisymmetric with respect to principal axis of symmetry
<i>E</i>	Doubly degenerate, two-dimensional irreducible representation
<i>T</i>	Triply degenerate, three-dimensional irreducible representation
<i>g</i>	Symmetric with respect to a center of symmetry
<i>u</i>	Antisymmetric with respect to a center of symmetry
1 (subscript)	Symmetric with respect to a C_2 axis that is perpendicular to the principal axis. Where there is no such axis the subscript indicates that reflection in a σ_v plane of symmetry is symmetric.
2 (subscript)	Antisymmetric with respect to a C_2 axis that is perpendicular to the principal axis. Where there is no such axis the subscript indicates that reflection in a σ_v plane of symmetry is antisymmetric.
<i>,</i> (prime)	Symmetric with respect to reflection in a horizontal plane of symmetry
<i>''</i> (double prime)	Antisymmetric with respect to reflection in a horizontal plane of symmetry
